Abstract

Depressive disorders are very common in clinical practice, with approximately 11.3 of all adults afflicted during any one year. Saffron is the world’s most expensive spice and apart from its traditional value as a food additive, recent studies indicate several therapeutic effects for saffron. It is used for depression in Persian traditional medicine. Our objective was to compare the efficacy of hydro-alcoholic extract of *Crocus sativus* (stigma) with fluoxetine in the treatment of mild to moderate depression in a 6-week double-blind, randomized trial. Forty adult outpatients who met the Diagnostic and Statistical Manual of Mental Disorders, fourth edition for major depression based on the structured clinical interview for DSM-IV and with mild to moderate depression participated in the trial. In this double-blind, single-center trial and randomized trial, patients were randomly assigned to receive capsules of saffron 30 mg/day (BD) (Group 1) and capsule of fluoxetine 20 mg/day (BD) (Group 2) for a 6-week study. Saffron at this dose was found to be effective similar to fluoxetine in the treatment of mild to moderate depression \((F=0.13, d.f.=1, P=0.71)\). There were no significant differences in the two groups in terms of observed side effects.

The results of this study indicate the efficacy of *Crocus sativus* in the treatment of mild to moderate depression. A large-scale trial is justified.

1. Introduction

Depression, which is thought to result from biochemical changes in the brain, is a common disease of adulthood. This affective disorder affects about 5% of the adult population in the USA at any specific time (Judd, 1995). As defined by the American Psychiatric Association, depression is a heterogeneous disorder often manifested with symptoms at the psychological, behavioral and physiological levels (American Psychiatric Association, 1994). The advent of the first antidepressants—the monoamine oxidase inhibitors (MAOIs) and tricyclic antidepressants (TCAs) in the 1950s and 1960s represented a dramatic leap forward in the clinical management of depression. The subsequent development of the selective serotonin reuptake inhibitors (SSRIs) and the serotonin norepinephrine reuptake inhibitor (SNRI) venlafaxine in the past decade and a half has greatly enhanced the treatment of depression by offering patients medications that are as effective as the older agents, but are generally more tolerable and safer in an overdose. The introduction of atypical antidepressants, such as bupropion, nefazadone, and mirtazapine, has added substantially to the available pharmacopoeia for depression (Donoghue and Tylee, 1996; Mac Donald, 1997). Concurrent with research into the neurobiology of depression comes the necessity to seek improved clinical outcomes for our patients. Nearly one-third of patients receive no benefit, and one-third does not experience com-
plete remission following an initial monotherapy trial with an antidepressant. Treatment resistance therefore remains a considerable problem, and the goal of treatment must be full remission, and not just symptom improvement (Richelson, 1994; Demyttenaere, 1997). Plant extracts are some of the most attractive sources of new drugs and have been shown to produce promising results for the treatment of depression (Ernst, 1995; De Smet and Nolen, 1996). As a therapeutically plant, saffron (Crocus sativus L. that belongs to the Iridaceae family) is considered an excellent stomach ailment and an antispasmodic, helps digestion and increases appetite. It also relieves renal colic, reduces stomachaches and relieves tension. In Persian tradition medicine is used for depression. Recent studies indicate its potential as an anti cancer agent and memory enhancer (Riss et al., 1996; Abe and Saito, 2000; Karimi et al., 2001; Abdullaev, 2002; Hosseinzadeh and Younesi, 2002). Many Persian medicinal plants textbooks refer to its antidepressant effect whereas there is no evidence-based document. Our objective was to compare the efficacy of saffron with fluoxetine in the treatment of mild to moderate depression in a 6-week double-blind and randomized trial.

2. Methods

This was a 6-week randomized and double-blind clinical trial. The investigation was conducted in the outpatient clinic of Roozbeh Psychiatric Hospital, Tehran University of Medical Sciences, Tehran, Iran, between January 2002 and March 2004.

2.1. Patients

Forty adult outpatients who met the Diagnostic and Statistical Manual of Mental Disorders, fourth edition (DSM-IV) (American Psychiatric Association, 1994) for major depressive disorder were included. Diagnosis was based on the structured clinical interview for DSM-IV remission, and not just symptom improvement (Richelson, 1994; Demyttenaere, 1997). All patients were between 35 and 40 years of age. The part of Crocus sativus L. that belongs to the Iridaceae family is considered an excellent stomach ailment and an antispasmodic, helps digestion and increases appetite. It also relieves renal colic, reduces stomachaches and relieves tension. In Persian tradition medicine for depression. Recent studies indicate its potential as an anti cancer agent and memory enhancer (Riss et al., 1996; Abe and Saito, 2000; Karimi et al., 2001; Abdullaev, 2002; Hosseinzadeh and Younesi, 2002). Many Persian medicinal plants textbooks refer to its antidepressant effect whereas there is no evidence-based document. Our objective was to compare the efficacy of saffron with fluoxetine in the treatment of mild to moderate depression in a 6-week double-blind and randomized trial.

2.2. Saffron capsule preparation

The saffron was used in this study was dedicated by Novin Zaferan Co. (Mashhad, Iran) and was identified by the Department of Cultivation and Development of Institute of Medicinal Plants, Tehran, Iran. The part of Crocus sativus that are being used as additive and also herbal medicine is stigma. The stigma’s extract was prepared as follow: 120 g of dried and milled stigmas were extracted with 1800 ml ethanol (80%) by percolation procedure in three steps then the ethanolic extract was dried by evaporation in temperature between 35 and 40 °C. Each capsule had dried extract of saffron (15 mg), lactose (filler), magnesium stearate (lubricant), and sodium starch glycolate (disintegrant). The dose of each capsule was calculated according to an animal study (Karimi et al., 2001). The extract was standardized by safranal. Each capsule had 0.30–0.35 mg safranal.

2.3. Study design

Patients underwent a standard clinical assessment comprising a psychiatric evaluation, a structured diagnostic interview and a medical history. Patients were randomized to receive capsule of saffron or capsule of fluoxetine in a 1:1 ratio using a computer-generated code. The assignments were kept in sealed, opaque envelopes until the point of allocation. The randomization and allocation process was done by the pharmacist of the Roozbeh hospital. In this double-blind, single-center trial, patients were randomly assigned to receive capsule saffron 30 mg/day (BD) (Group 1) or capsule fluoxetine 20 mg/day (BD) (Group 2) for a 6-week study. Patients were assessed by a third year resident of psychiatry at baseline and after 1, 2, 4 and 6 weeks after the medication started. The principal measure of the outcome was the 17-item HAM-D: The rater used standardized instructions in the use of HAM-D. The mean decrease in HAM-D score from baseline was used as the main outcome measure of response of depression to treatment. Throughout the study the person who administrated the medications, rater and patients were blind to assignments. No significant differences were identified among patients randomly assigned to the Group 1 or 2 conditions with regard to basic demographic data including age and gender (Table 1). Thirty-eight patients completed the trial. In the saffron and fluoxetine group the number of dropouts was one patient. No significant difference was observed in the two groups in terms of dropout (P = 1.51).

2.4. Side effects

Side effects were systematically recorded throughout the study and were assessed using a checklist administered by a resident of psychiatry on day 3, 7, 14, 21, 28 and 42 (Table 2).

2.5. Statistical analysis

A two-way repeated measures analysis of variance (time–treatment interaction) was used. The two groups as a between-subjects factor (group) and the five weekly measurements during treatment as the within-subjects factor (time) were considered. This was done for HAM-D total scores. In addition, a one-way repeated measures analysis of variance with a two-tailed post-hoc Tukey mean comparison test were performed in the change from baseline for HAM-D scores in each group. To compare the two groups at baseline and the outcome of two groups at the end of the trial, an unpaired Student’s t-test with a two-sided P-value was used. Results are presented as mean ± S.E.M. Differences were considered significant with P < 0.05. To compare the demographic data and frequency of side effects between the protocols, Fisher’s exact test (two-sided) was performed. To consider, α = 0.05, β = 0.2, the final difference between the two groups at least score of five on the HAM-D total scores that is clinically detectable, S = 5 and power = 80%, the sample size was calculated at least 15 in each group. Intention to treat (ITT) analysis with last observation carried forward (LOCF) procedure was performed.

3. Results

3.1. Efficacy: saffron versus fluoxetine

The mean ± S.E.M. scores of two groups of patients are shown in Fig. 1. There were no significant differences between the two groups in week 0 (baseline) on the Hamilton Depression Rating Scale (t = 0.31, d.f. = 38, P = 0.75). The difference between the two protocols was not significant as indicated by the effect of group, the between-subjects factor (Greenhouse–Geisser correction; d.f. = 1, F = 0.13, P = 0.71). The behavior of the two treatments was homogeneous across the time (groups–by–time interaction, Greenhouse–Geisser correction; F = 1.82, d.f. = 1.73, P = 0.17). In addition, a one-way repeated measures analysis of variance showed a significant effect of both protocols on Hamilton Depression Rating Scale scores (P < 0.0001). In the saffron and fluoxetine group post-hoc comparisons showed a significant change from week on the Hamilton Depression Rating Scale scores. The difference between the two protocols was not significant at the endpoint (week 6) (t = 1.68, d.f. = 38, P = 0.09). The changes at the endpoint compared to baseline were: −12.20 ± 4.67 (mean ± S.D.) and −15.00 ± 5.88 for saffron and fluoxetine, respectively. No significant difference was observed on the change of scores of the Hamilton Depression Rating Scale at week 6 compared to baseline in the two groups (t = 1.66, d.f. = 38, P = 0.10).

3.2. Clinical complications and side effects

Nine side effects were observed over the trial. The difference between the saffron and fluoxetine in the frequency of side effects was not significant (Table 2).

4. Discussion

The morbidity and mortality associated with depression are considerable and continue to increase. Depression currently ranks fourth among the major causes of disability.
May well confirm the application of saffron as an alternative treatment for depression in Persian traditional medicine and these results deserve further investigations.

Compelling interest
None declared.
